Class 9 Mini-Project

1. Exploratory data analysis

Preparing the data

```
# Save your input data file into your Project directory
# (hid data with {r, results='hide'} to conserve pdf pages).
fna.data <- "WisconsinCancer.csv"
# Complete the following code to input the data and store as wisc.df
wisc.df <- read.csv(fna.data, row.names=1)
wisc.df

# Examine the data (hid data with {r, results='hide'} to conserve pdf pages).
wisc.df

# Examine the data with 'head()'
head(wisc.df)
```

##	diagnosis	radius_mean	texture_mean	perimeter_mean	area_mean

```

Exploratory data analysis

Q1. How many observations are in this dataset?

```
nrow(wisc.data)
```

There are 569 observations.

```
## [1] 569
```

Q2. How many of the observations have a malignant diagnosis?

212 have a malignant diagnosis.

```
table(diagnosis)
```

```
## diagnosis
##      B      M
## 357 212
```

```
colnames(wisc.df)
```

class examples on retrieving column names.

```
## [1] "diagnosis"          "radius_mean"
## [3] "texture_mean"       "perimeter_mean"
## [5] "area_mean"          "smoothness_mean"
## [7] "compactness_mean"   "concavity_mean"
## [9] "concave.points_mean" "symmetry_mean"
## [11] "fractal_dimension_mean" "radius_se"
## [13] "texture_se"         "perimeter_se"
## [15] "area_se"            "smoothness_se"
## [17] "compactness_se"     "concavity_se"
## [19] "concave.points_se"  "symmetry_se"
## [21] "fractal_dimension_se" "radius_worst"
## [23] "texture_worst"      "perimeter_worst"
## [25] "area_worst"         "smoothness_worst"
## [27] "compactness_worst"  "concavity_worst"
## [29] "concave.points_worst" "symmetry_worst"
## [31] "fractal_dimension_worst"
```

```
grep("_mean", colnames(wisc.df))
```

class example using ‘grep’ to help us find patterns we are interested in.

```
## [1] 2 3 4 5 6 7 8 9 10 11
```

Q3. How many variables/features in the data are suffixed with `_mean`?

10.

```
length(grep("_mean", colnames(wisc.df)))
```

```
## [1] 10
```

2. Principal Component Analysis

Performing PCA

```
# Check column means and standard deviations  
colMeans(wisc.data)
```

##	radius_mean	texture_mean	perimeter_mean

Interpreting PCA results

Create a biplot of the wisc.pr using the biplot() function.

Q7. What stands out to you about this plot? Is it easy or difficult to understand? Why?

```
biplot(wisc.pr)
```

This plot is crowded and difficult to interpret.

```
# principal component (PC1/PC2)
# hid data with {r, results='hide'} to conserve pdf pages.
wisc.pr$x
```

```
# Scatter plot observations by components 1 and 2
plot(wisc.pr$x, col = diagnosis ,
     xlab = "PC1", ylab = "PC2")
```

Q8. Generate a similar plot for principal components 1 and 3. What do you notice about these plots?

Although similar, PC1 vs PC2 displays less overlap between the data sets.

```
# Repeat for components 1 and 3
plot(wisc.pr$x[, c(1, 3)], col = diagnosis,
     xlab = "PC1", ylab = "PC3")
```

ggplot

```
# Create a data.frame for ggplot
df <- as.data.frame(wisc.pr$x)
df$diagnosis <- diagnosis

# Load the ggplot2 package
library(ggplot2)

# Make a scatter plot colored by diagnosis
ggplot(df) +
  aes(PC1, PC2, col=diagnosis) +
  geom_point()
```

Variance explained

```
# Calculate variance of each component
pr.var <- wisc.pr$sdev^2
head(pr.var)
```

```
## [1] 13.281608 5.691355 2.817949 1.980640 1.648731 1.207357
```

```
sum.pr <- sum(pr.var)
```

```
# Variance explained by each principal component: pve
pve <- pr.var/ sum.pr
pve
```

Calculate the variance explained by each principal component by dividing by the total variance explained of all principal components. Assign this to a variable called pve and create a plot of variance explained for each principal component.

```
## [1] 4.427203e-01 1.897118e-01 9.393163e-02 6.602135e-02 5.495768e-02

Q10. What is the minimum number of principal components required to explain 80% of the variance of the data?

```
x$importance[3,] >= 0.8
```

Minimum number of principal components is 5.

```
##   PC1  PC2  PC3  PC4  PC5  PC6  PC7  PC8  PC9  PC10  PC11  PC12  PC13
## FALSE FALSE FALSE FALSE TRUE  TRUE  TRUE  TRUE  TRUE  TRUE  TRUE  TRUE

## PC27 PC28 PC29 PC30
## TRUE  TRUE  TRUE  TRUE
```

```
PC80 <- which(x$importance[3,] >= 0.8)
PC80[1]
```

```
## PC5
##    5
```

3. Hierarchical clustering

First scale the wisc.data data and assign the result to data.scaled.

```
# Scale the wisc.data data using the "scale()" function
data.scaled <- scale(wisc.data)
```

Calculate the (Euclidean) distances between all pairs of observations in the new scaled dataset and assign the result to data.dist.

```
data.dist <- dist(data.scaled)
```

Create a hierarchical clustering model using complete linkage. Manually specify the method argument to hclust() and assign the results to wisc.hclust.

```
wisc.hclust <- hclust(data.dist, method="complete")
```

Results of hierarchical clustering

Q11. Using the plot() and abline() functions, what is the height at which the clustering model has 4 clusters?

```
plot(wisc.hclust)
abline(h=19, col="red", lty=2)
```

Cluster Dendrogram

height = 19

data.dist
hclust (*, "complete")

Selecting number of clusters

Use `cutree()` to cut the tree so that it has 4 clusters. Assign the output to the variable `wisc.hclust.clusters`.

```
wisc.hclust.clusters <- cutree(wisc.hclust, k=4)
table(wisc.hclust.clusters, diagnosis)
```

```
##              diagnosis
## wisc.hclust.clusters  B  M
##                   1 12 165
##                   2  2  5
##                   3 343  40
##                   4  0  2
```

Q12. Can you find a better cluster vs diagnoses match by cutting into a different number of clusters between 2 and 10?

```
wisc.hclust.clusters2 <- cutree(wisc.hclust, k = 2, 10)
table(wisc.hclust.clusters2, diagnosis)
```

```
##              diagnosis
## wisc.hclust.clusters2  B  M
##                   1 357 210
##                   2  0  2
```

Q13. Which method gives your favorite results for the same `data.dist` dataset? Explain your reasoning.

```
wisc.pr.hclust <- hclust(data.dist, method="ward.D2")
plot(wisc.pr.hclust)
```

The 'ward.D2' method appears to give a better result of the same data.dist data set. The dendrogram displays the clusters generated from squaring the dissimilarities. This gives a cleaner dendro-

Cluster Dendrogram

```
data.dist
hclust (*, "ward.D2")
gram.
```

```
wisc.pr.hclust.C <- hclust(data.dist, method="complete")
plot(wisc.pr.hclust.C)
```

Cluster Dendrogram

```
data.dist
hclust (*, "complete")
```

4. OPTIONAL: K-means clustering

```
wisc.km <- kmeans(scale(wisc.data), centers= 2, nstart= 20)
table(wisc.km$cluster, diagnosis)
```

```
##      diagnosis
##      B      M
## 1  14 175
## 2 343  37
```

Q14. How well does k-means separate the two diagnoses? How does it compare to your hclust results?

```
table(wisc.hclust.clusters, wisc.km$cluster)
```

Fewer false positives/negatives.

```
##
## wisc.hclust.clusters  1  2
##      1 160 17
##      2  7  0
##      3 20 363
##      4  2  0
```

5. Combining methods

Clustering on PCA results

```
grps <- cutree(wisc.pr.hclust, k=2)
table(grps)
```

```
## grps
##    1    2
## 184 385
```

```
# We can do a cross-table by giving the table() function two inputs.
# TP (true positive = 164) FP (false positive = 20)
# TN (true negatives = 337) FP (false positive = 48)
table(grps, diagnosis)
```

```
##      diagnosis
## grps    B    M
##    1  20 164
##    2 337  48
```

```
plot(wisc.pr$x[,1:2], col=grps)
```

```
g <- as.factor(grps)
levels(g)
```

```
## [1] "1" "2"
```

```
g <- relevel(g,2)
levels(g)
```

```
## [1] "2" "1"
```

```
# Plot using our re-ordered factor
plot(wisc.pr$x[,1:2], col=g)
```

OPTIONAL

```
library(rgl)
plot3d(wisc.pr$x[,1:3], xlab="PC 1", ylab="PC 2", zlab="PC 3", cex=1.5, size=1, type="s", col=grps)

## Use the distance along the first 7 PCs for clustering i.e. wisc.pr$x[, 1:7]
wisc.dist <- dist(wisc.pr$x[, 1:7])
wisc.pr.hclust <- hclust(wisc.dist, method="ward.D2")
plot(wisc.pr.hclust)
```

Cluster Dendrogram

```
wisc.dist
hclust (*, "ward.D2")
```

Q15. How well does the newly created model with four clusters separate out the two diagnoses?

```
wisc.pr.hclust.clusters <- cutree(wisc.pr.hclust, k=2)
table(wisc.pr.hclust.clusters, diagnosis)
```

```
##           diagnosis
## wisc.pr.hclust.clusters  B  M
##           1  28 188
##           2 329  24
```

Q16. How well do the k-means and hierarchical clustering models you created in previous sections (i.e. before PCA) do in terms of separating the diagnoses? Again, use the table() function to compare the output of each model (wisc.km\$cluster and wisc.hclust.clusters) with the vector containing the actual diagnoses.

```
table(wisc.km$cluster, diagnosis)
```

```
##      diagnosis
##        B  M
##    1  14 175
##    2 343  37
```

```
table(wisc.hclust.clusters, diagnosis)
```

```
##           diagnosis
## wisc.hclust.clusters  B  M
##           1   12 165
##           2    2   5
##           3 343  40
```

```
##                4    0    2
```

#6. Sensitivity/Specificity ### **Q17.** Which of your analysis procedures resulted in a clustering model with the best specificity? How about sensitivity? #### It appears that the best specificity comes from using 'hclust' and we get the best sensitivity with 'kmeans'.

```
(175)/(175+14)
```

calculating sensitivity $TP/(TP+FN)$

```
## [1] 0.9259259
```

7. Prediction

```
#url <- "new_samples.csv"
url <- "https://tinyurl.com/new-samples-CSV"
new <- read.csv(url)
npc <- predict(wisc.pr, newdata=new)
npc
```

```
##          PC1          PC2          PC3          PC4          PC5          PC6          PC7
## [1,]  2.576616 -3.135913  1.3990492 -0.7631950  2.781648 -0.8150185 -0.3959098
